Why to use ML for power flow learning?

Hoeffding's Inequality

For acceptable error $arepsilon=2 imes 10^{-3}$ & 95% confidence, number of samples needed are

 $M \ge 0.5 \log(2/\beta) \varepsilon^{-2} \ge 200,258$

Running Newton-Raphson load flow 200, 258 times is 'challenging'

More so in limited time to quantify 'operational risk'

Solution \implies A Fast Evaluating ML proxy of Power Flow

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三日 のの⊙

How good an ML tool can be for risk estimation?

If NRLF-based statistical estimation have error ε_h , then same number of ML evaluations will achieve |True Expected Violation - Estimated Expected Violation|

with confidence $1 - \beta$, under a condition.

Main Result

Performance using 200, 258 NRLFs \equiv Performance using 801, 029 ML Evaluations Using Gaussian process (GP) model $L\varepsilon_m(1-\delta) + M\delta + \varepsilon_h \approx 2 \times \varepsilon_h$

Condition: Probability of the absolute difference between true & predicted voltage (by ML) being larger than ε_m is less than or equal to δ .

6/25

Why Gaussian Process (GP) is suitable for Power Flow learning?

GP regression uses **prior knowledge** about a function along with data, to **predict unobserved values** and **quantifying prediction uncertainty**.

Provide performance guarantee without requiring ground truth solutions
 Has low training data requirement due to prior knowledge infusion

A Closed-form Power Flow Approximation Framework is

- Flexible ⇒ Non-linear forms with complexity-accuracy trade-off
- Easy to Evaluate \implies Faster numerical calculations
- Non-parametric \implies Works within a power injection range or hypercube
- Differentiable \implies Can be fed into optimization problems
- Interpretable \implies Should provide insights into physical system

Essentially an **explicit expression** of voltage as a function of power injection which provides a **probabilistic performance guarantee** for risk estimation

イロト 不同 トイヨト イヨト 三日 ろくや

GP Working Idea: In Brief

• Prior Knowledge: Smooth Function

$$k(x_i, x_j) = \tau^2 \exp\left\{\frac{-\|x_i - x_j\|_2^2}{2\ell^2}\right\}$$

• Predict unobserved values: Mean

Thickest Shade of Blue

• Prediction uncertainty: Variance

Lighter blue – lower probability

• Performance Guarantee[†]

$$\mathbb{P}\left\{\left|V(\mathbf{s}) - [\mu(\mathbf{s}) + \gamma\sigma(\mathbf{s})]\right| \ge \varepsilon_m\right\} \le \delta(\gamma)$$

Image: A matrix and a matrix

[†] Considering the power flow function is a GP.

[↑] C. K. Williams and C. E. Rasmussen, Gaussian processes for machine learning. MIT press Cambridge, MA, 2006, vol. 2, no. 3.

CFPF: Forms

$$V_{j}(\mathbf{s}) = \begin{bmatrix} k(\mathbf{s}^{1}, \mathbf{s}) & \dots & k(\mathbf{s}^{N}, \mathbf{s}) \end{bmatrix} \boldsymbol{\alpha}_{j}$$
Variable $\mathbf{s} = [\mathbf{p}; \mathbf{q}]$ Constant

How Do Forms Look Then?

Simple, Standard Forms

- Linear:
$$\mathbf{v} = A\mathbf{s} + b$$
 - Quadratic: $V_j(\mathbf{s}) = \mathbf{s}^T M \mathbf{s} + \mathbf{m}^T \mathbf{s} + r$

More Complex but Accurate Forms

$$V_j(\mathbf{s}) = \sum_{i=1}^N \alpha_j(i) \beta^i$$

where, $\beta^{i} = \tau^{2} \exp\left(-\|\mathbf{s}^{i} - \mathbf{s}\|^{2}/2l^{2}\right)$: Gaussian Kernel

 ${f v}$: Node Voltage Vector; M : Sensitivity Matrix; ${f m}$: Slope Vector;

 ${f s}$: Node Power Injection Vector

Using Network-Structure to Achieve Additive GP Architecture

- Neighboring power injections have highly correlated effect on node voltages
- Effect of far away power injections is approximately equal to sum of individual effects

EL OQO

Active Learning: Lower Samples and Stopping Criteria

- ★ What: Learning by successively selecting the next training point 'intelligently'
- ★ Why: To speed-up the learning process using unlabeled data i.e. only input data needed ⇒ Low Sample Complexity ⇒ Less Power Flow Samples Needed
- ★ Concept: Next training point is the one which has maximum uncertainty in underlying function

 $\mathbf{s}^{t+1} = rgmax_{\mathbf{s}\in\mathcal{L}} \sigma_f^t(\mathbf{s}) o \mathtt{Only}$ Function Evaluation

Provides a Proxy of Error → Stopping Criteria

Finding maximum variance point for large-dimensional input space is hard ⇒ Used mostly up to 20-dimensions ⇒ Power systems have 100s of uncertain power injections

Theorem

Given for an ML model $\mathbb{P}\{|V(\mathbf{s}^i) - \hat{V}(\mathbf{s}^i)| > \varepsilon_m\} \le \delta$ with $\delta \in (0, 1)$ for any $\mathbf{s} \in S$, and $h(\cdot)$ is a Lipschitz continuous function with Lipschitz constant L, then the error in expected value estimation using the ML model, for any $\mathbf{s} \in S$, is bounded with probability greater than $1 - \beta$ as

$$\left| \mathbb{E}[h_p(\mathbf{s})] - \widehat{\mathbb{E}}[h_m(\mathbf{s})] \right| \le L\varepsilon_m(1-\delta) + M\delta + \varepsilon_h$$

where, $\beta \in (0,1)$, $\varepsilon_h = \sqrt{\frac{\log (2/\beta)}{2N}}$, $M > |h_p(\mathbf{s}) - h_m(\mathbf{s})|$, and N number of samples.
